

Health Risks of Particle Pollution

Particle pollution is a lethal air pollutant. Particle pollution is made up of microscopic specks of soot, metals, acids, dirt, pollen, molds, and aerosols that are tiny enough to inhale.¹ These particles are many times smaller than the diameter of a human hair, as shown in the illustration.

Particles penetrate deep into the lungs and even into the bloodstream, leading to tens of thousands of premature deaths, heart attacks and asthma attacks every year. The World Health Organization concluded in 2013 that breathing particle pollution causes lung cancer.²

Breathing particles can trigger asthma attacks; cause lung cancer; increase the risk of heart attacks and strokes; damage lung tissue and airways; increase hospital visits for respiratory and cardiovascular problems; and even kill.³

Someone in every family is vulnerable.

Children, teens, people aged 65 and older, people with low incomes and people with chronic lung disease, such as asthma and COPD (which includes chronic bronchitis and emphysema), are more vulnerable to the risk of harm from particles.

People with diabetes, heart disease, high blood pressure, coronary artery disease, and congestive heart failure also face higher risk from particle pollution.

Less particle pollution benefits everyone. In a recent, large study, scientists found that reductions in particle pollution in U.S. cities between 2000 and 2007 increased the average lifespan by about 2 months.⁴

We must clean up the sources of particles. Particles come from wide-ranging sources, including coal-fired power plants, industrial boilers, diesel vehicles, wildfires and woodstoves.

Cleaning up particle pollution saves lives and protects public health.
