Health Risks of Ozone Pollution

Ozone is the nation’s most widespread air pollutant. Ozone (O\textsubscript{3}) is a gas molecule made up of three oxygen atoms. Sometimes called smog, ozone pollution forms in the atmosphere when gases that come out of tailpipes, smokestacks, oil and gas extraction and other sources react in the presence of sunlight. The gases that react to form ozone are volatile organic compounds, nitrogen oxides, and carbon monoxide. Ozone levels typically rise between May and October when higher temperatures, increased sunlight, and stagnant atmospheric conditions transform air pollutants into ozone. Rising temperatures from climate change will make it harder to reduce ozone.

When a person inhales ozone pollution, it reacts chemically (“oxidizes”) with the body’s internal tissues, causing inflammation, like a “sunburn” of the lung. Ozone acts as a powerful respiratory irritant at the levels frequently found across the nation, especially during the summer months.

Millions of people are vulnerable to the health threats from ozone pollution. Five groups of people are especially vulnerable to the effects of breathing ozone:

- children and teens;
- anyone 65 and older;
- people with existing lung diseases, such as asthma and COPD;
- people with cardiovascular disease;
- people—even healthy adults—who work or exercise outdoors.

Independent scientists and U. S. Environmental Protection Agency (EPA) concluded that ozone pollution posed multiple, serious threats to health. The EPA engaged a panel of expert scientists, the Clean Air Scientific Advisory Committee, and the public in a four-year process to help them assess all available research. Their findings, published in 2013, are highlighted in the box below, along with a few of the hundreds of studies they cited.

**Ozone Pollution Poses Serious Health Threats**

- Causes respiratory harm (e.g. worsened asthma, worsened chronic obstructive pulmonary disease [also known as COPD, which includes emphysema and chronic bronchitis])
- Likely to cause early death
- Likely to cause cardiovascular harm (e.g. heart attacks, strokes, heart disease, congestive heart failure)
- May cause harm to the central nervous system
- May cause reproductive and developmental harm

Based on these findings, EPA strengthened the national standards for ozone in 2015, although the American Lung Association and health and medical allies called for stronger limits than EPA adopted.
